WEEK 1 LECTURE 1: INTRODUCTION

- Mental disorder implies abnormal behaviour that is not only statistically rare, unacceptable to society, causes distress and/or is maladaptive, but that it also stems from an underlying dysfunction or illness.
 - Abnormal behaviour is not necessarily a mental disorder
- For a behaviour resulting from an internal dysfunction to qualify as a mental disorder it needs an additional value component: it needs to be causing harm to the individual.
- DSM-5 have given an importance to culture in a way that previous editions have not- because of the influence of culture the whole concept of mental illness is invalid.
- Even if there is agreement on the concept of abnormality it is often applied inconsistently.
 - There are problems of definition and application
 - Abnormality is not black or white- there is a continuum.
- In order to constitute an abnormal behaviour, a behaviour needs to be one or more of the following:
 1. Statistical rarity- deviate from the average
 2. Deviant- different, extreme, unusual, socially unacceptable
 3. Distress- unpleasant and upsetting
 4. Dysfunction or maladaptive- causes interference with life- often incorporated in diagnostic criteria for the various mental disorders.
 5. Danger- poses risk of harm to self or others.

DIFFERENT WAYS TO UNDERSTAND ABNORMAL PSYCHOLOGY:

- Subjective interpretation- listen to what the person reports, their experiences and behaviour and match with diagnostic criteria.
- Objective tests- depends on scores on tests.

CULTURAL FORMULATION INTERVIEW

- A set of 16 questions which clinicians use to assess impact of culture on an individual's clinical representation.
- Includes experience of membership in diverse social groups- not only person's ethnic culture but also faith and occupational culture.
- Considers aspects of background that affect perspective e.g. migration, language, sexual orientation.
- Takes into account the influence of family friends and community on a person's illness and experience.

IMPORTANT TERMS:

- **PREVALENCE:** how many people in a population have the condition
- **INCIDENCE:** how many cases occur in a given period of time.
- **SEX RATIO:** percentage of men to women with disorder
- **COURSE OF CONDITION:** chronic v episodic v time limited

- **ONSET:** acute v insidious. Age of onset.
- **PROGNOSIS:** Anticipated course of disorder
- **ETIOLOGY:** study of origins.

HISTORICAL DEVELOPMENT OF NOTION OF ABNORMAL BEHAVIOUR:

1. Super-natural

- In the stone ages
- Possible causes: demons, ghosts and evil spirits; moon and stars affect mental health; mental illness as punishment from god; imbalance of yin and yang.

2. Biological

- Mental illness explained by physical causes
- Ancient Egypt- used hysteria to explain illness in women
- Hippocrates conceptualised mental illness as a brain or hereditary disease.
- Prior to 20th century- mental illness was equated with insanity and people were treated in mental asylums often by non-medically trained individuals.
- Believed insanity to be a single disease that progressed from one major symptoms to another over time.
- Many doctors believed that all mental disturbances would eventually be identified as having a biological origin, in the form of some bacterial or viral infection, contact with toxic agents or structural brain abnormalities.

3. Psychological

- Mental illness explained by psychological processes (manner in which people interpret the environment, their conscious or unconscious beliefs and motivations, or their learning history)
- Approach we are most concerned about today

CURRENT PSYCHOLOGICAL MODELS OF ABNORMALITY:

| MODEL | CAUSE | GOAL OF THERAPY | TREATMENT | CRITICISM |
|----------------------|--|--|---|--|
| PHYSIOLOGICAL | Genetics, damage to brain, altered neurochemistry | Remove source | Drugs, ECT, diet and exercise. | Reductionist -possibility of relapse when terminating drugs |
| PSYCHODYNAMIC | Unconscious processes- people adopt strategies to avoid anxiety e.g. repression, denial, | Making the unconscious conscious through psychoanalysis e.g. recalling | Interpretation of unconscious clues via free association, dream analysis, analysis of | Exclusion of environmental and cultural factors. |

| | | | | |
|--------------------------------------|--|--|--|--|
| | projection, reaction formation. | emotional trauma | resistance in therapy, analysis of transference. | |
| COGNITIVE BEHAVIOURAL | Faulty learning and aberrant thought patterns- Possible interpretations of event lead to different emotional and behavioural responses. Individuals adopt cognitive distortions. | Change thinking and behaviour- those that are not working for the patient. | Classical, operant conditioning, modelling. Identifying and challenging irrational and maladaptive thoughts. | Focus on cognitions and behaviour at the expense of emotion. Emphasis on present rather than past. |
| HUMANISTIC | Incongruence or discrepancy between self-image and experience or behaviour. | Humans choosing and searching for meaning- self-actualisation. | Approach therapeutic relationship with unconditional positive regard (rogers), motivation for behaviour is meeting needs (Maslow), gestalt techniques (perls). | How to explain deviant behaviour. |
| SOCIO-CULTURAL & SYSTEMIC | Focus on the whole rather than the parts. Individual in relationship with others. Discord between parts of system. | To change to a more functional system with more diversity. | Working with internal system (holistic approaches), & external system e.g. family to develop more adaptive interactions. | |

- Depending on disorder some models and treatment paradigms seem to have better success.
