

## NOTES FOR THIS REVISION DOCUMENT:

- This revision document contains a concise summary of EVERY lecture. They are NOT in the order in which they were given, but rather grouped into a more logical order (e.g. MHC and genetics, primary and secondary immunodeficiencies lectures grouped together). ALL lectures are in here.
- Summaries are divided into 'key facts' (KFs), then Short-Answer Questions (SAQs) and flashcards made by myself.
- Good luck! 😊

## LECTURES COVERED:

<b>LECTURE 2 (08/08/19): Viruses as pathogens.....</b>
<b>LECTURE 3 (13/08/19): Receptors.....</b>
<b>LECTURE 4 (15/08/19): Transport .....</b>
<b>LECTURE 5 (20/08/19): Viral immune response and VZV study .....</b>
<b>LECTURE 6 (22/08/19): Diagnosis of viral infections.....</b>
<b>LECTURE 7 (29/08/19): Viral infections of the CNS .....</b>
<b>LECTURE 8 (03/09/19): Emerging Viruses.....</b>
<b>LECTURE 9 (05/09/19): Dengue Virus.....</b>
<b>LECTURE 10 (10/09/19): Alpha herpesviruses .....</b>
<b>LECTURE 11 (12/09/19): Beta and Gamma Herpesviruses .....</b>
<b>LECTURE 12 (17/09/19): Gastroviruses .....</b>
<b>LECTURE 13 (19/09/19): HIV/AIDS – Epidemiology and Evolution .</b>
<b>LECTURE 14 (24/09/19): Viruses and Cancer .....</b>
<b>LECTURE 15 (26/09/19): Influenzavirus.....</b>
<b>LECTURE 17 (10/10/19): Vector-borne viral diseases .....</b>
<b>LECTURE 18 (15/10/19): Epidemiology and Outbreak Control .....</b>
<b>LECTURE 19 (17/10/19): Antivirals.....</b>
<b>LECTURE 20 (22/10/19): Oncolytic viruses .....</b>
<b>LECTURE 21 (24/10/19): Hepatitis Viruses .....</b>
<b>LECTURE 22 (29/10/19): Gene Therapy .....</b>
<b>LECTURE 23 (31/10/19): Vaccines Against Viruses .....</b>
<b>LECTURE 24 (05/11/19): Virus-specific immunotherapy.....</b>

## SAMPLE:

### L5 KF: VZV AND VIRAL IMMUNE RESPONSE

- First line of defence = physical/chemical barriers = passive and immediate. Second line = innate immune response, requires activation, 24 hrs, no memory and non-specific. Third line = adaptive, requires activation, 3 days, memory and specific.
- When have viral infection: IFN- $\alpha$ /B respond first, then NK cells, then virus titer peaks and goes down, then virus-specific CTLs, then Ab (remains).

- As an overview of the IR to viral infection: cell use PRRs to detect viral infection and release cytokines (IFN) and chemokines – establish AV state and recruit innate cells. Neutros and NK cells migrate to SOI. DC takes up virus and activates CD8s and CD4s specific to virus (clonal expansion). Effector T cells migrate to SOI. CTLs kill infected cells. Virus-specific Abs are produced by B cells (get help from CD4). Once infection is cleared, many effector cells die, but some memory T and B cells remain.
- TLRs are type 1 integral membrane proteins. Virus specific ones are located within endosomes: TLR3 for dsRNA (HIV), TLR7/8 for ssRNA, TLR9 for CpG DNA. Other TLRs lie on the membrane. Result of TLR activation – NF-kB or IRF transcription factors.
  - NF-kB (through Myd88) leads to pro-inflamm cytokines, chemokine expression, upregulation of endothelial adhesion molecules, upregulation of co-stim (→ adaptive IR). Therefore mostly acute inflammation and stimulation of adaptive IR.
  - IRF route (through TRIF) = expression of type 1 IFNs → induce an antiviral state.
- **Innate IR:**
  - **Cytokines** – regulate innate and adaptive immunity. Mostly pro-inflammatory such as IFN $\alpha$  and B, TNF, IL-1 and IL-6, IFN- $\gamma$ .
  - **Type 1 IFNs** = alpha and beta = mediate early innate IR. These have four functions:
    - Induce AV state in cell and its uninfected neighbours
      - Induces Protein Kinase R (PKR but still requires activation by dsRNA) that phosphorylates EIF2 $\alpha$  and inhibits TL – blocks new infectious virion assembly.
      - Induces 2',5'-oligo A synthetase (but still requires activation by dsRNA) – recruits RNAase A – chops up viral RNA.
      - Activation and multimerisation of Mx GTPases – inhibit/prevent gene expression and virion assembly.
    - Increase MHC I expression → link to initiating adaptive.
    - Activate NK cells
    - Stimulate macro and Ab responses → link to adaptive.
  - **NK cells** – lymphocytes that lack Ag-specific surface receptors non-specific). Type 1 ILCs. Respond to IL-12 and IL-15. Found in blood and lymphoid tissue. Kill tumour and virus-infected cells. Function earlier in course of infection than CTLs and recognise targets in different ways. Packed full of cytotoxic granules and express CD16 (FcyRIII).
    - Recognise infected cell via CD16 (look for Abs bound to cell) and induce ADCC, or via MHC I reduction (indicates viral presence).
    - Activated through action of 2 receptor types:
      - An activating receptor – binds heterogenous group of ligands e.g. IgG, HLA, etc. has an ITAM motif. Sends an activating signal to cell.
      - An inhibitory receptor – binds to MHC I if present – has an ITIM motif. Sends an inhibitory signal to cell that dominates activating signal.
      - Therefore when NK cell encounters a normal cell, both receptors will be bound, and NK will not activate. If encounters infected cell, MHC will be downregulated, so only activating receptor will bind and NK will activate = signal to kill.
    - Effector functions: CTL-like mechanism (lyse cell through granzymes/perforin), secrete IFN- $\gamma$  and TNF (stim macro, Ab, more NK, Th1 formation) or ADCC (FcyRIII cross-linking of Ab-opsonized cells and granzymes release). ADCC is active during the intracellular phase of viral infection.
- **Adaptive IR:**
  - CTLs:
    - Recognise virally-infected cells via MHC I Ag presentation and are activated. From a naïve state, require two activating signals from APC = MHC I with antigenic

peptide and co-stim binding to CD28. APCs phagocytose an infected viral cell, therefore perform cross-presentation to express the extracellular antigen on MHC I. Naïve CD8 activates and upregulates chemokine receptors, selectin ligands, integrins, etc.

- Move to periphery – endothelial cells at SOI upregulate selectins and integrin ligands in response to TNF and IL-1. As the CTLs are mature, can re-activate at SOI without co-stim, just require MHC I (still TCR, CD8, LFA-1 and iCAM-1 interaction).
  - Killing is antigen specific and contact-dependent. Can often have many CTLs contacting one infected cells = many synapses = conjugate formation.
  - MAIN mechanism of killing is via perforin/granzymes. After synapse formation and specific recognition, CTL redistributes cytoskeleton – targeted exocytosis of granules containing perforin and granzymes. Perforin polymerises in the lipid bilayer of the target cell to form a pore – allows entry of granzymes and osmotic lysis. Granzymes are serine proteases – granzymes B cleaves the aspartate residues thus activates pro-caspases and induces apoptosis. CTL detaches so not affected by own action (neighbouring cells are also unharmed due to tight synapse).
  - CTLs can also perform Fas/FasL killing and secrete cytokines, but this was not mentioned in this virology lecture.
- Abs:
    - Plays different roles depending on where the virus is within the host.
    - Neutralisation = extracellular virus = Ab binds to virus and prevent its binding with a cell surface receptor.
    - ADCC = intracellular virus = Ab binds antigens on the surface of target cells (viral glycoproteins embedded in the membrane) = opsonizes cell and promotes clearance by phagocytes OR via ADCC (NK cells). ADCC occurs if NK cells cross-link (regulatory mechanism) the Fc portion. Cells die via apoptosis.
- Viruses hide/subvert the IR by:
    - Avoiding recognition by Ab e.g. influenzavirus high mutation rate
    - Hiding from the immune system:
      - Hide in neuron e.g. HSV and VZV
      - Establish latent/dormant infection with limit gene expression e.g. herpesviruses
    - Directly infect cells and destroy/alter cells of the immune system e.g. HIV, CMV
    - Encode immunomodulatory gene products that modulate innate/adaptive IR
      - Affect response/activation of the IR
      - Produce “dummy” decoy molecules

#### L5 SAQ:

1. Which TLRs are important for viral recognition? Where are they? What do they recognise?
2. Compare results of NFκB and IRF activation
3. Describe the three mechanisms of the innate IR?
4. Describe how type 1 IFNs work (four methods)
5. Describe the two mechanisms of the adaptive IR?
6. Compare activation of NK cells and CTLs
7. Describe VZV infection, its three phases, how it transmits round the body.
