

Lectures 1: Recombinant Proteins

Lectures:

Students should:

- Understand the basic features of recombinant expression systems used in modern research.
- Be able to describe why different systems are chosen for different proteins and provide examples.
- Be able to describe the structure and function of antibodies and engineered forms
- Understand the basics of how monoclonal antibodies are developed.
- Understand the how and why monoclonal antibodies are “humanised”
- Be able to use examples to describe the importance of antibodies as therapeutic agents.

		Top Selling Therapeutic Proteins in 2010 (\$US billion)						
		# (09)	Name	Target/mechanism	Type	Company	Indication	Sales
		1 (1)	Etanercept	TNF α	Fc fusion TNFR2 ECD	Amgen Wyeth	Immune diseases	7.287
		2 (3)	Bevacizumab	VEGF	Humanized IgG	Genentech Roche Chugai	Cancer	6.973
		3 (4)	Rituximab	CD20	Chimeric IgG	Genentech Biogen-IDEC Roche	Cancer	6.859
		4 (5)	Adalimumab	TNF α	Human IgG	Abbott Eisai	Immune diseases	6.548
		5 (2)	Infliximab	TNF α	Chimeric IgG	Centocor (J&J) Schering-Plough Mitsubishi Tanabe	Immune diseases	6.520
		6 (7)	Trastuzumab	Her2	Humanized IgG	Genentech Chugai Roche	Cancer	5.859
Insulin Glargine- made in yeast		7 (8)	Insulin glargine	Insulin receptor	Modified insulin	Sanofi-Aventis	Diabetes	4.834
		8 (6)	Epoetin alfa	EPO-R	Human EPO	Amgen Ortho Biotech Kyowa Hakko Kirin	Anemia	4.590
Epoetin alfa- made in mammalian cells		9 (9)	Pegfilgrastim	G-CSF receptor	PEGhuman G-CSF	Amgen	Neutropenia	3.558
		10 (11)	Ranibizumab	VEGF	Humanized Fab	Genentech Novartis	AMD	3.106
Pegfilgrastim- made in bacteria		11 (10)	Darbepoetin alfa	EPO-R	Modified human EPO	Amgen Kyowa Hakko Kirin	Anemia	2.995
		12 (12)	Interferon beta-1a (Avonex)	Interferon beta receptor	Human interferon beta-1a	Biogen Idec	Multiple sclerosis	2.518
		13 (13)	Interferon beta-1a (Rebif)	Interferon beta receptor	Human interferon beta-1a	Merck Serono	Multiple sclerosis	2.297
		14 (17)	Insulin aspart	Insulin receptor	Modified insulin	Novo Nordisk	Diabetes	2.198

Why do we need to use different host organisms?

- cost
- ethics
- folding and modifications...making the correct protein
 - Insulin: di-sulfide bonds, (yeast glycosylate but it's a different process)
 - Pegfilgrastim: normally glycosylated in humans but not in bacteria however wasn't important for the function

Why make proteins recombinantly?	<ul style="list-style-type: none"> • can't get it from endogenous sources • for efficient and selective purification • quality control (large batches and they need to be consistent) • to optimize activity/efficacy
Heterologous hosts for protein expression	<ul style="list-style-type: none"> • Bacteria • Yeast (<i>Pichia</i> sp, <i>Sachromyces cerevisiae</i>) • Plants • Baculovirus <ul style="list-style-type: none"> ○ virus infects insect cells and makes proteins • Cultured mammalian cells • Animals <ul style="list-style-type: none"> ○ e.g. goats- purified from goat milk

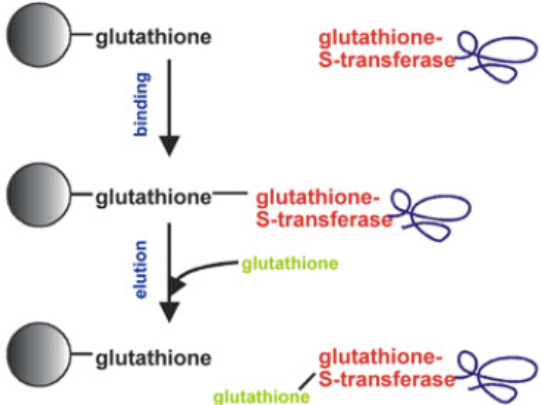

Bacterial Expression	Pros	Cons
	<ul style="list-style-type: none"> widely used easy manipulation rapid growth ∴ cheap many commercial vectors and tags to add to proteins to enhance purification 	<ul style="list-style-type: none"> no post-translational modifications <ul style="list-style-type: none"> because there's no secretory pathway (no membrane bound organelles) most proteins expressed are non-soluble <ul style="list-style-type: none"> large quantities may disrupt folding and result in formation of fusion bodies high endotoxin content <ul style="list-style-type: none"> need efficient purification processes

Expression as fusion proteins

Most target proteins are not simple to purify from a cell

- Alternate approach
 - genetically fuse the **gene** encoding the target protein with a gene encoding a **purification tag**.
 - Fusion proteins enhance solubility
 - When the chimeric protein is expressed, the tag allows for specific capture of the fusion protein. This will allow the purification of virtually any protein **without any prior knowledge of its biochemical properties**.
- Common tags (which bind to the Affinity column):
 - glutathione S-transferase**
 - In Biotechnology: fusion proteins of interest can undergo purification from the cells due to high glutathione affinity
 - metabolic isozymes which catalyze the conjugation of the reduced form of glutathione (GSH) to xenobiotic substrates for the purpose of detoxification
 - Glutathione is an essential metabolic molecule that is produced in the liver of humans and animals
 - maltose binding protein**
 - binds to maltose
 - His-tag** (separated by protease cleavage site for on-column cleavage)
 - binds to nickel
 - poly-Histidine tag: comprises 6 – 14 histidines and is typically fused to the N- or C-terminal end of a target protein
 - hydrophilic and flexible
 - ↑ solubility of target proteins
 - rarely interfere with protein's function

<p>Plasmid Vectors</p>	<p><i>e.g. for Glutathione S transferase (GST) tag to isolate and purify Tim9....sequence contained a sequence which could be cut by Thrombin (a protease) thus we could have purified Tim9</i></p>	<p>Principle GST-tag protein purification</p> 				
<p>Pros and Cons for using tags in fusion proteins</p>	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="width: 50%;">Pros</th> <th style="width: 50%;">Cons</th> </tr> </thead> <tbody> <tr> <td style="vertical-align: top;"> <ul style="list-style-type: none"> • improve protein yield • prevent proteolysis • facilitate protein folding • increase solubility (the fusion domain) • ease of purification </td> <td style="vertical-align: top;"> <ul style="list-style-type: none"> • lower protein yields <ul style="list-style-type: none"> ○ cleavage domain may not be complete thus protease can't cleave • alteration in biological activity (few extra amino acids) • cleavage/removing the fusion partner may require expensive proteases <ul style="list-style-type: none"> ○ <i>e.g.</i> Factor Xa → enterokinase </td> </tr> </tbody> </table>	Pros	Cons	<ul style="list-style-type: none"> • improve protein yield • prevent proteolysis • facilitate protein folding • increase solubility (the fusion domain) • ease of purification 	<ul style="list-style-type: none"> • lower protein yields <ul style="list-style-type: none"> ○ cleavage domain may not be complete thus protease can't cleave • alteration in biological activity (few extra amino acids) • cleavage/removing the fusion partner may require expensive proteases <ul style="list-style-type: none"> ○ <i>e.g.</i> Factor Xa → enterokinase 	
Pros	Cons					
<ul style="list-style-type: none"> • improve protein yield • prevent proteolysis • facilitate protein folding • increase solubility (the fusion domain) • ease of purification 	<ul style="list-style-type: none"> • lower protein yields <ul style="list-style-type: none"> ○ cleavage domain may not be complete thus protease can't cleave • alteration in biological activity (few extra amino acids) • cleavage/removing the fusion partner may require expensive proteases <ul style="list-style-type: none"> ○ <i>e.g.</i> Factor Xa → enterokinase 					
<p>Where to target expression of recombinant proteins in bacteria?</p>	<p><u>Direct Expression (Cytosol):</u></p> <ul style="list-style-type: none"> • <i>E. coli</i> cytoplasm is a reducing environment <ul style="list-style-type: none"> ○ ∴ cannot get proper disulfide S-S bonds <p><u>Secretion (periplasm or medium):</u></p> <ul style="list-style-type: none"> • fuse target protein with a peptide/protein which targets in for secretion • periplasm offers a more oxidizing environment ∴ proteins fold better • Limitations: <ul style="list-style-type: none"> ○ limited capacity for secretion (0.1-0.2% total cell protein compared to 10% produced intracellularly) ○ limited capacity for post-translational modifications of proteins 	<p>bacteria do have disulfide bond forming capabilities but only in the periplasm. We can't secrete that much protein into the periplasm thus we don't rely on bacterial disulfide bond formation</p>				
<p>Inclusion Bodies in <i>E. coli</i></p>	<ul style="list-style-type: none"> • Dense particles which contain precipitated (insoluble) • Formation depends on: <ul style="list-style-type: none"> ○ protein synthesis rate ○ growth conditions • Protein refolding options exist but <u>poor</u> success rates
